

EU wide extrapolation of UK cost of biofuels calculations

Malcolm Fergusson, December 2011

The two reports by the IISD (1) calculate the cost of biofuels mandates to consumers and the taxpayer in Germany and the UK, respectively. These reports have produced figures for expected differences in production costs in 2020, assuming compliance with EU 10% 'biofuel' targets. This Excel spreadsheet contains calculations for extrapolating these figures to the EU 27 level.

To achieve this, total demand projections and a petrol/diesel split for 2020 were derived from the European Commission's annual *Energy Trends* forecasts. Intermediate years were then interpolated on a straight line basis from the 2010 baseline. For the 10% split scenario, the levels of bioethanol and biodiesel were then calculated on a simple 10% of energy content basis from petrol and diesel respectively, and converted to litres. The B7 limit scenario followed the same track for the early years until the 7% energy content ceiling was reached, at which point the ethanol percentage was allowed to increase more rapidly to maintain the 10% energy content basis overall. The cost difference in pence per litre from the UK's Impact Assessment was then applied to each fuel for each of the four fuel price scenarios set out.

The following Excel spreadsheets contain the data sets and calculations made. Final EU wide costs for 2020 and cumulative 2010 to 2020 are given in the sheet 'EU time series' (see Sheet 9). Final UK costs 2010-2020 are contained in Sheet 8 'UK time series'.
